SUMMARY	17

INTRODUCTION

A survey of Laxá í Aðaldal between Laxárþirkjun and Skjálfandi was performed during the summer of 1986. Environmental conditions such as substrate composition, water velocity, degree of sedimentation, and amount of interstitial space between submerged rocks were recorded. Potential habitat improvement sites were noted and the results of this analysis are enclosed.

Justification for recommended habitat designs is omitted in this report although it will follow in the comprehensive final report.

Habitat enhancements are primarily for juvenile Salmon. They have been designed to be unobtrusive and in compliance with environmental restrictions.

Following the location maps for habitat sites, are details showing construction specifications for each type of habitat structure. Wherever a variety of structure types is possible, alternatives are presented to account for available materials.

SPECIFICATIONS

ROCK PLACEMENT - UNANCHORED

The following typical cross-section illustrates correct placement of unanchored rocks.

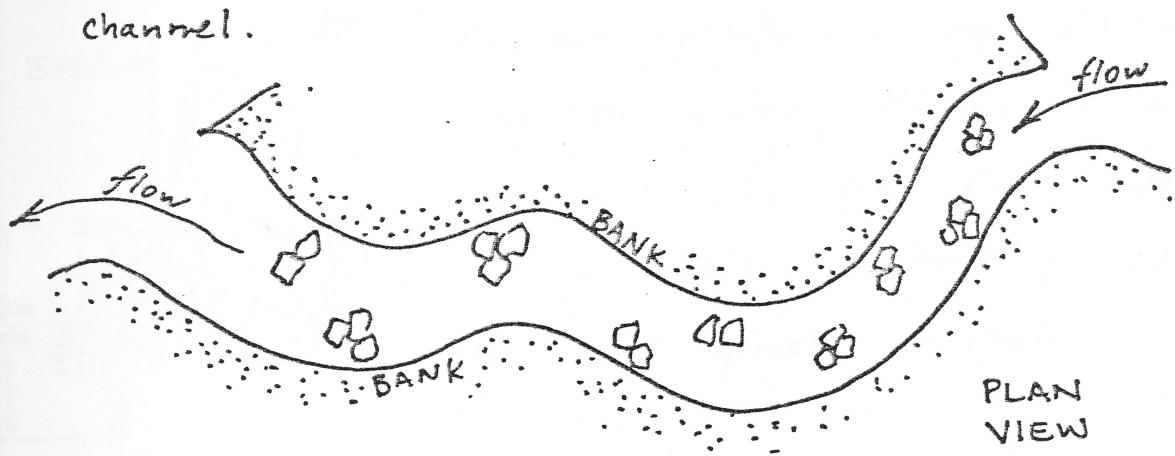

Rock should be distributed evenly, allowing for interstitial spaces. Use of rocks smaller than those specified may result in water flow blockage. Water velocities should be above 0.1 m/sec. between rocks. Sedimentation of the bottom layer of rocks may occur although uppermost interstitial spaces will remain open.

Rocks should be placed where indicated on maps 2-9, in regions of steady water velocity (between 0.1 and 0.5 m/sec.) and away from sediment deposition areas.

Where rock is placed throughout a channel, groupings of 2 or 3 rocks are desirable.

The following illustrates rock placement in a channel.

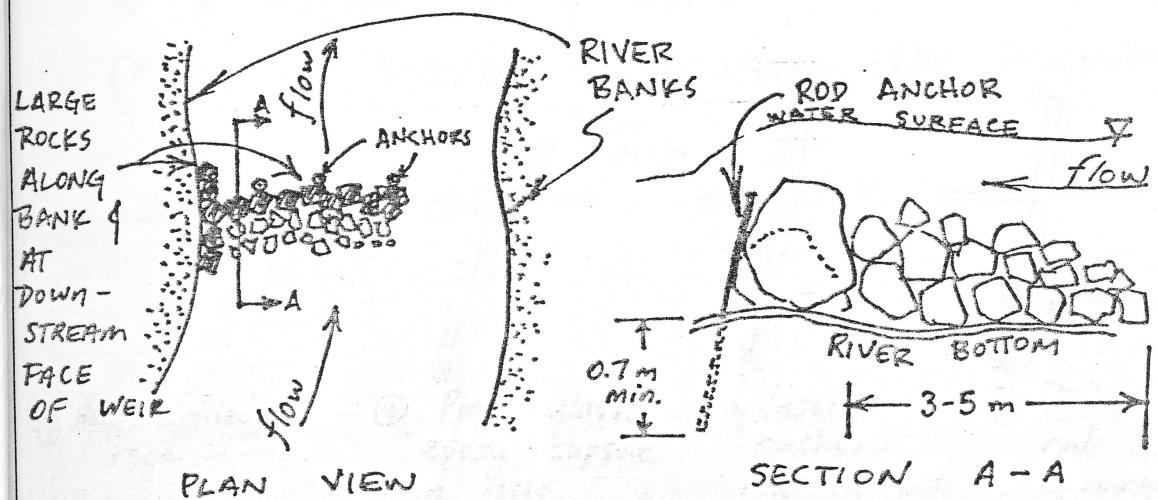

ANCHORED ROCK PLACEMENT

TYPE A : Continuous Weir

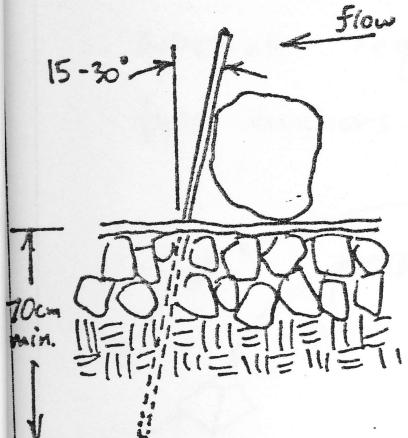

Anchored rocks are specified because seasonal river flow increases will transport unanchored substrate.

In general, continuous weirs consist of the structure shown below.

A variety of anchoring methods is presented so that environmental conditions

and material availability are accounted for.

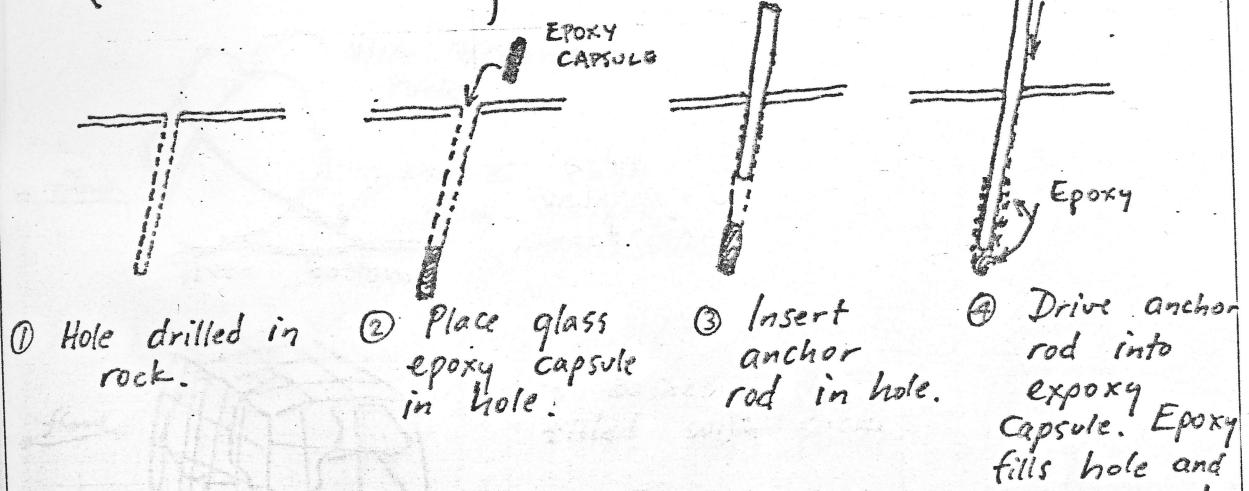

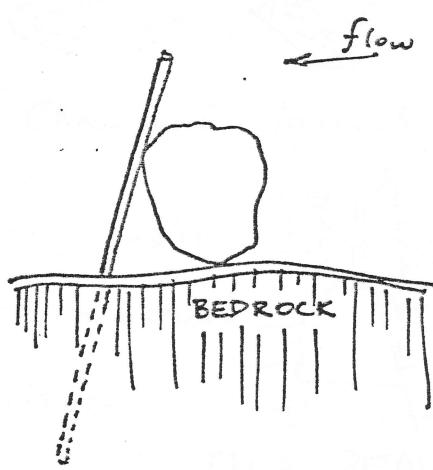

Concrete reinforcing rod, 20 mm dia. or greater, driven 70 cm or until solid and immovable. Anchor works in hard-packed rock and gravel substrate.

Where bedrock anchors are needed, a hole may be power-drilled.

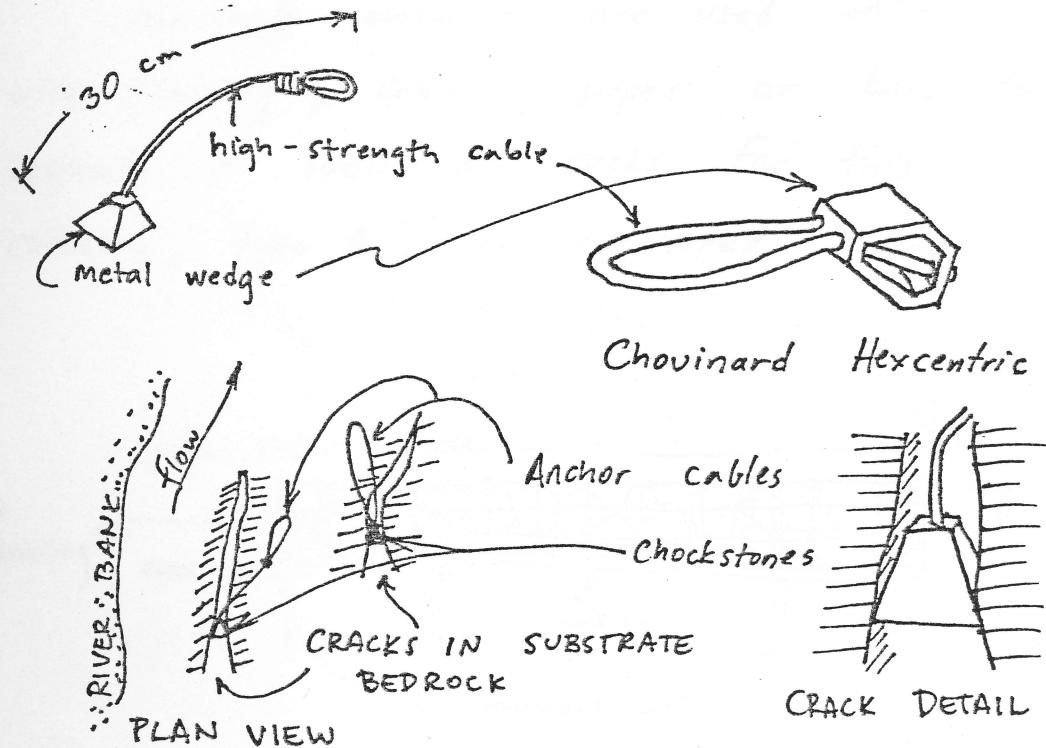

The rod is either pounded into the undersize diameter hole or is set with mortar or a concrete epoxy capsule.*

(* Used in building construction. Use illustrated:)

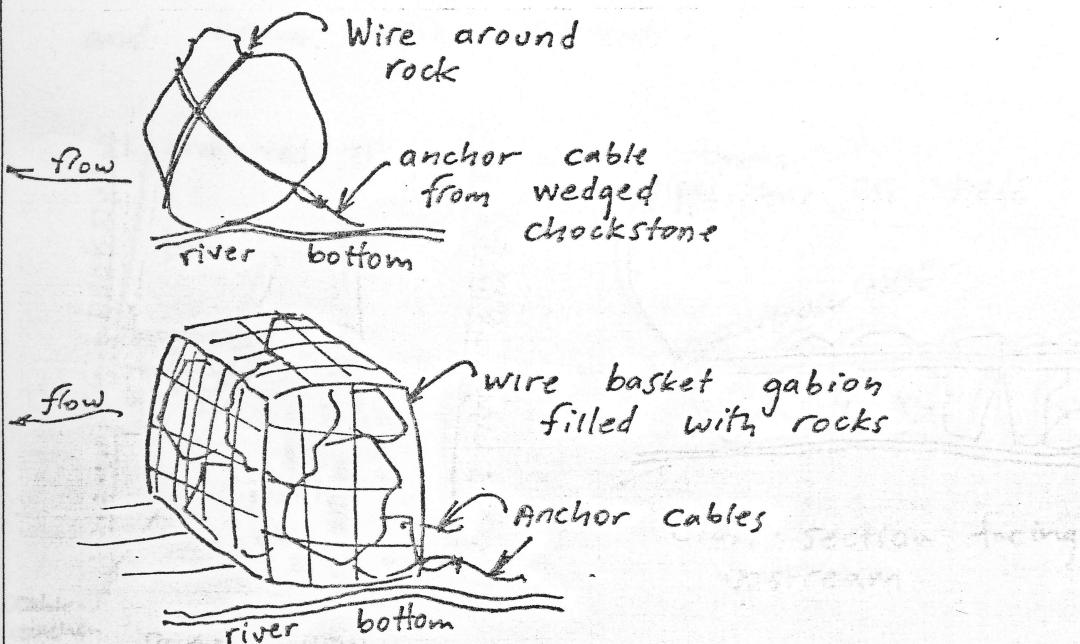

For rock drilling equipment in Húsavík, consult with the city engineer's office.

An alternative anchoring system for bedrock substrate requires mountain climber's chock stone type anchors or similar.

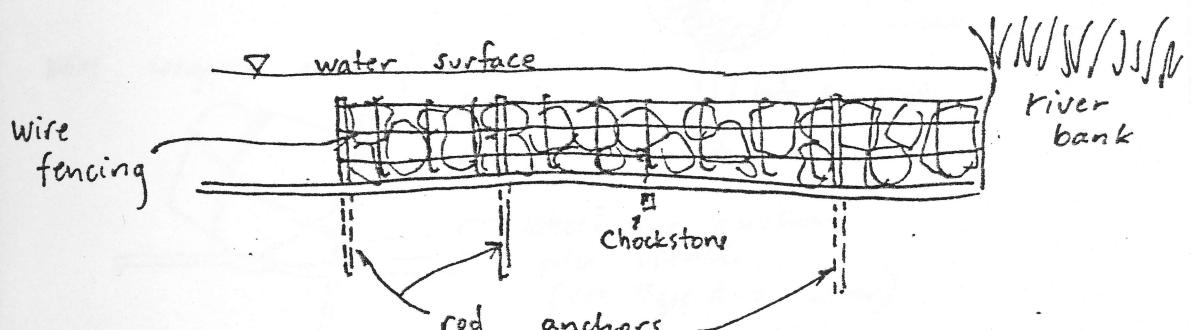

Anchor cables are attached to a connected-weir structure or wire-wrapped rocks.

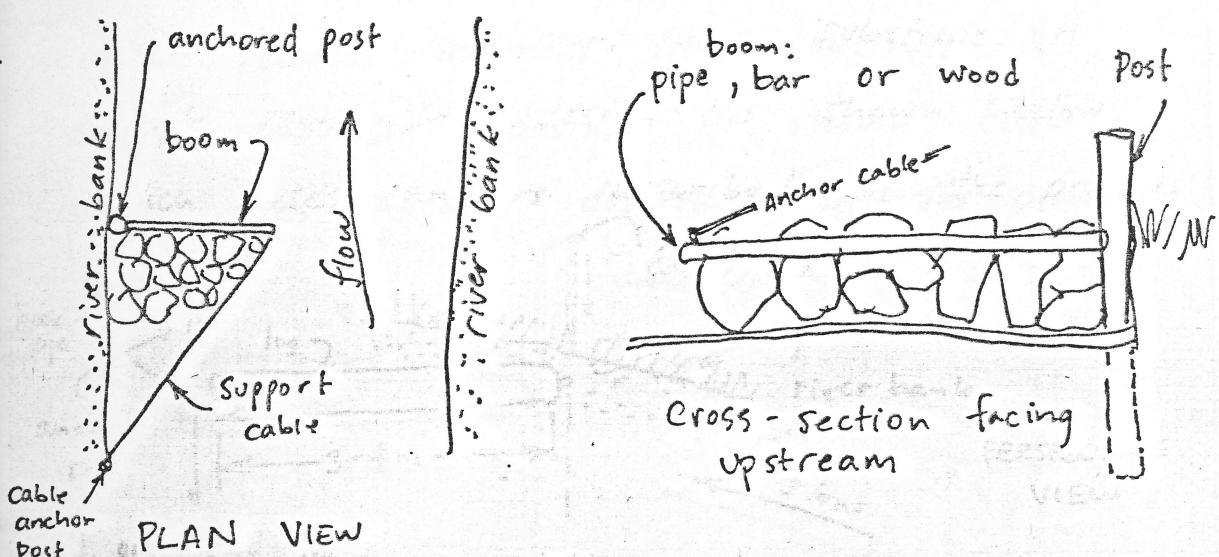

Chockstone anchors should be placed at 50 cm intervals or used in conjunction with rod anchors.

Substrate anchors are used with wire fencing, cables, pipes or bars to restrain a weir of rocks for this category, type A, of anchored rocks.

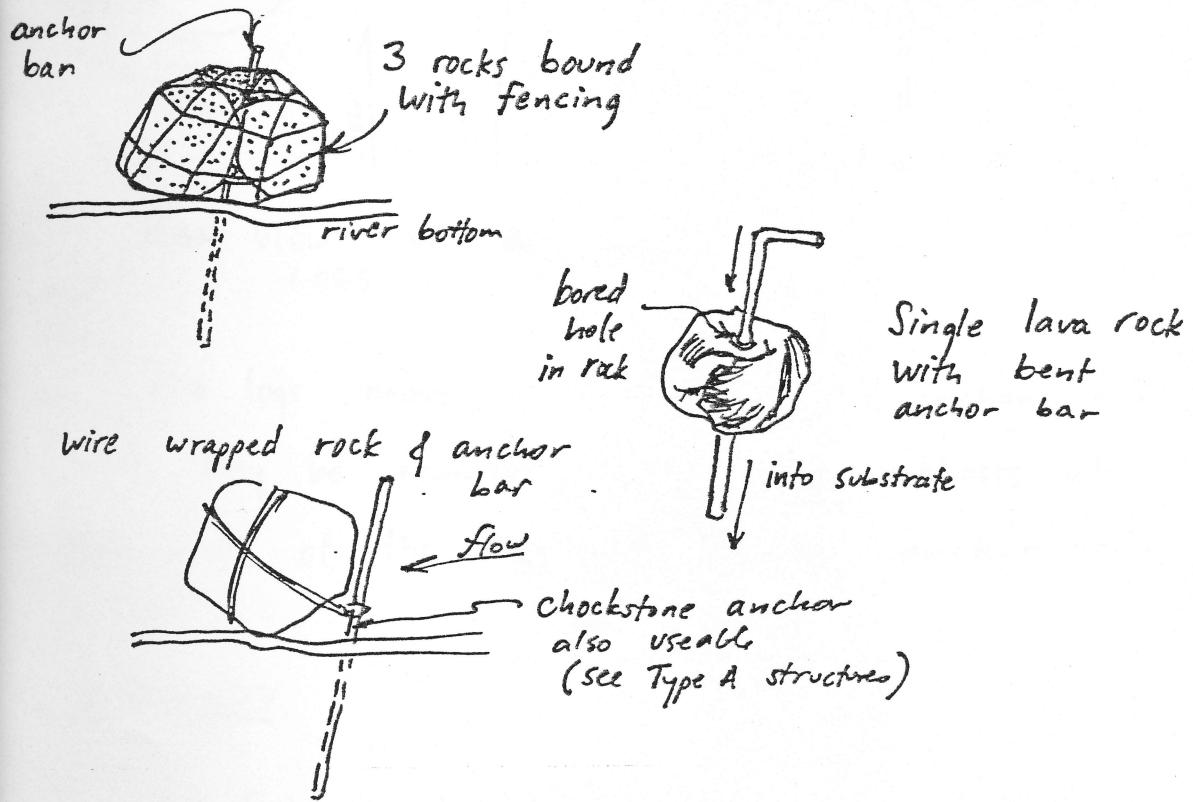

Cross - Section facing upstream

Anchored weir using bank anchors only and boom weir restraint:

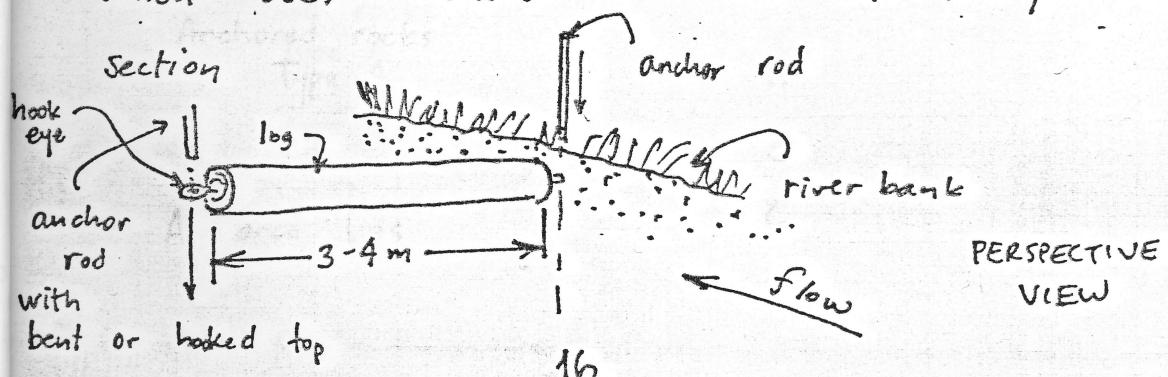

TYPE B : Individual Rocks

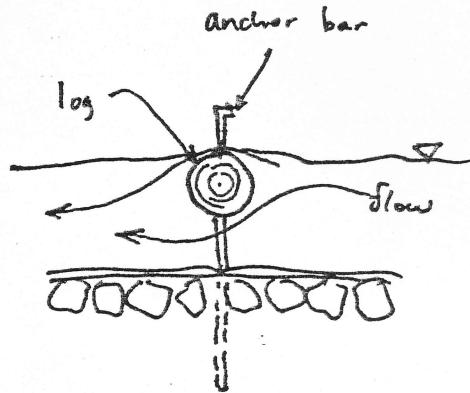

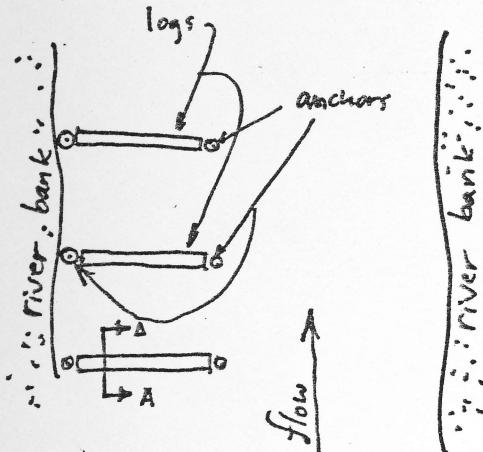

Single or small groupings of rocks are anchored using techniques illustrated below.

ANCHORED LOGS

Logs are used to generate flow turbulence which releases sediment from substrate. A simple removable design is shown below which uses anchors described in the previous

PLAN VIEW OF ANCHORED LOGS

The logs move vertically on their anchor bars and may be removed by lifting eyebolts at the ends of the logs off of the anchor rods.

SUMMARY

The following habitat improvements are recommended as the result of a field survey of Laxá i Adaldal during the summer of 1986.

Type of habitat	Number of sites
Loose Rock	14
Anchored rocks	
Type A	4
Type B	5
Anchored logs	6
